

Ecological site R030XB115NV GYPSIC SODIC LOAM 3-5 P.Z.

Last updated: 3/10/2025
Accessed: 08/30/2026

General information

Provisional. A provisional ecological site description has undergone quality control and quality assurance review. It contains a working state and transition model and enough information to identify the ecological site.

Ecological site concept

This site occurs on shoulders and backslopes of eroded pediments hills, and fan remnants. Slopes may range from 2 to 30 percent (on short backslopes) but slope gradients of 2 to 8 percent are typical. Elevations are 1450 to about 2400 feet. The soil associated with this site are shallow to very shallow and somewhat excessively drained. The soils formed in residuum derived from gypsiferous sedimentary rocks. This is a group concept and provisional STM that also covers the following ecological sites: R030XB109NV and R030XB117NV.

Similar sites

R030XY013NV	SHALLOW SILTY ATCO dominant plant on site
R030XB131NV	CALCAREOUS PEDIMENT 3-5 P.Z. ATCO-AMDU2 codominant shrubs; soils not significantly affected by gypsum
R030XB006NV	LOAMY 5-7 P.Z. ATCO-AMDU2 codominant
R030XY025NV	SODIC FLAT ATCO-ATHY codominant shrubs
R030XY040NV	SODIC TERRACE ATCO-LYCIU codominant; ATPO and ATCA2 important shrubs
R030XB114NV	SODIC LOAM 3-5 P.Z. ATCO-SUMO codominant shrubs

Table 1. Dominant plant species

Tree	Not specified
------	---------------

Shrub	(1) <i>Atriplex confertifolia</i> (2) <i>Petalonyx parryi</i>
Herbaceous	(1) <i>Enceliopsis argophylla</i>

Physiographic features

This site occurs on shoulders and backslopes of eroded pediments hills, and fan remnants. Slopes may range from 2 to 30 percent (on short backslopes) but slope gradients of 2 to 8 percent are typical. Elevations are 1450 to about 2400 feet.

Table 2. Representative physiographic features

Landforms	(1) Pediment (2) Hill (3) Fan remnant
Elevation	440 – 730 m
Slope	0 – 30 %

Climatic features

The climate of the Mojave Desert has extreme fluctuations of daily temperatures, strong seasonal winds, and clear skies. The climate is arid and is characterized with cool, moist winters and hot, dry summers. Most of the rainfall falls between November and April. Summer convection storms from July to September may contribute up to 25 percent of the annual precipitation. Average annual precipitation is 3 to 5 inches. Mean annual air temperature is 70 to 75 degrees F. The average growing season is about 300 to 360 days.

Table 3 Representative climatic features

Frost-free period (average)	360 days
Freeze-free period (average)	
Precipitation total (average)	130 mm

Influencing water features

There are no influencing water features associated with this site.

Soil features

The soil associated with this site are shallow to very shallow and somewhat excessively drained. The soils formed in residuum derived from gypsiferous sedimentary rocks. Soil series associated with this site include Drygyp and Guardian. Drygyp has a petrogypsic horizon 7 to 65 inches. Guardian has a gypsic horizon from 2 to 19 inches.

Table 4. Representative soil features

Parent material	(1) Residuum – rock gypsum
Surface texture	(1) Gypsiferous fine sandy loam (2) Gypsiferous sandy loam
Family particle size	(1) Loamy
Drainage class	Somewhat excessively drained
Permeability class	Very slow to moderately rapid
Soil depth	10 – 50 cm
Surface fragment cover <=3"	0 – 10 %
Surface fragment cover >3"	Not specified
Available water capacity (0-101.6cm)	2.54 – 6.6 cm
Calcium carbonate equivalent (0-101.6cm)	0 – 10 %
Electrical conductivity (0-101.6cm)	Not specified
Sodium adsorption ratio (0-101.6cm)	Not specified
Soil reaction (1:1 water) (0-101.6cm)	7.4 – 8.4
Subsurface fragment volume <=3" (Depth not specified)	0 – 10 %

Subsurface fragment volume >3" (Depth not specified)	Not specified
---	---------------

Ecological dynamics

Although shadscale is typically the dominant plant on this site, Parry sandpaper plant and Fremont dalea are also important shrubs. Silverleaf sunray is abundant. California bearpoppy may be present but it is relatively uncommon.

Gypsic soils are generally weakly aggregated which can result in serious erosion. The severity of the erosion is dependent on the gypsum content (FAO 1990). Gypsiferous soils are generally structureless, low in organic matter, and may become unstable in water making them a poor medium for plant growth. Gypsic horizons, however, can also be strongly aggregated and form hard crusts that control erosion and sometimes impede the downward movement of water and extension of roots (FAO 1990). The continuous petrogypsic horizon plays a significant role in plant community dynamics by increasing the available water holding capacity of the soil. These soils are high in sodium and have approximately 50% ground cover of microbiotic crusts.

Gypsic crusts formed from sulfate minerals are common across this ecological site. Crusts form in the soils due to the lack of sufficient water to remove soluble salts (Dong et al. 2007). Microtopography created by crusts can form microcatchments for water, positively influencing soil moisture, causing suspended sediment to settle out, as well as, reinforcing the formation of soil crusts. Interactions between microbiotic crusts and vascular plants are complex. They can be mutualistic, competitive, or neutral (Williams 1994). Soil crusts can encourage seedling establishment and survival, due to increased water holding capacity and availability of macronutrients (Belnap 1995). Crusts can also act as a competitor. Seeds may require morphological adaptations in order to penetrate and establish in well developed microbiotic crusts (Williams 1994). This relationship will help keep non-natives out of the system, under undisturbed conditions, while native plants will thrive because they have evolutionary adaptations to persist in this environment.

Development of microbiotic crusts are successful increasers of soil stability because they are an accretionary phenomenon in an otherwise erosional setting (Williams 1994). Litter and microbiotic crusts increase infiltration and protect the soil surface from wind and water erosion (Belnap 1995). The micro-environment created by microbiotic crusts facilitate an increase in macronutrients and is associated with increased plant vigor and productivity (Williams 1994). Microbiotic crusts are also important for facilitating symbiotic plant-fungi-soil interactions, including the fixation of carbon and nitrogen.

Anthropogenic impacts including OHV's are the primary disturbance impacting the vegetation on this site. Microbiotic soil crusts are well adapted to growing in severely limited environments, but are poorly adapted to compressional disturbances such as recreational activities including biking and hiking (USGS 2006). Recreational activities disturb the soil and break up microbiotic surfaces leading to increased wind and water erosion, decreased infiltration, soil stability, nutrient availability and changes in the plant community composition. In addition to damaging the microbiotic soil crust, increased anthropogenic disturbance results in soil compaction. Soil compaction reduces soil aggregates and pore spaces which are important for soil stability and infiltration (Belnap 1995). Vigor and reproduction of native plants, including shadscale, will suffer under these conditions. Anthropogenic disturbances are vectors or propagule introduction of non-native species. Potential invasive species on this site include redstem stork's bill, African mustard and red brome.

Recreational impacts can be particularly devastating to these sites due to the presence of sensitive plant species like the Las Vegas bearpoppy and the silverleaf sunray. Recent surveys of the Las Vegas bearpoppy, have reported approximately 120 populations growing in the Mojave Desert region. It has been previously suggested that this species is restricted to soils with high gypsum content (Mistretta et al. 1996). However, the Las Vegas bearpoppy is not a true gypsophile, but actually a gypsova (a species that can occur on soil with or without gypsum) (Drohan and Merkler 2009). Distribution of this rare plant is more likely constrained by aridity and available soil moisture. The Las Vegas bearpoppy is commonly found on sites susceptible to erosion with high risk of runoff and low aggregate stability, these factors combined with soil chemistry results suggest that this species is highly adapted to survive in extremely limiting environments less tolerable to other species (Drohan and Merkler 2009). Approximately 27 percent of the known populations are experiencing significant impacts due to recreational activities. The Las Vegas bearpoppy is able to colonize disturbed sites. However, recruitment of this species may be episodic controlled by timing of precipitation events. Colonization and emergence of new individuals is likely explained by multiple factors related to soil moisture (Drohan and Merkler 2009). Silverleaf sunray is also commonly found growing on gypsiferous soils. Management decisions must be carefully considered in order to protect sensitive species that are uniquely adapted to gypsic soil conditions.

The mean fire return interval for shadscale communities ranges from 35 to 100 years. Shadscale communities are usually unaffected by fire because of low fuel loads, although a year of exceptionally heavy winter rains can generate fuels by producing a heavy stand of annual forbs and grasses. Increased presence of non-native annual grasses, such as cheatgrass, can alter fire regimes in shadscale communities by increasing fire frequency under wet to near-normal summer moisture conditions. When fire does occur, the effect on the ecosystem may be extreme. Shadscale is fire intolerant and it does not readily recover from fire, except for establishment through seed.

State and transition model

Additional community tables

Table 5. Community 1.1 plant community composition

Group	Common Name	Symbol	Scientific Name	Annual Production ()	Foliar Cover (%)
Grass/Grasslike					
1	Perennial grasses			1-11	
Forb					
2	Primary Perennial forbs			4-34	
	silverleaf sunray	ENAR	<i>Enceliopsis argophylla</i>	4-34	—
3	Secondary Perennial forbs			1-18	
	California bearpoppy	ARCA4	<i>Arctomecon californica</i>	1-7	—

Animal community

Livestock Interpretations: This site has limited value for livestock grazing, due to the low forage production and steep slopes. Shadscale tends to be browse tolerant. Heavy grazing during the winter and/or spring reduces shadscale. Die-off can also occur during extended periods of high precipitation. Shadscale is tolerant of early spring light-intensity browsing. Stocking rates vary over time depending upon season of use, climate variations, site, and previous and current management goals. A safe starting stocking rate is an estimated stocking rate that is fine tuned by the client by adaptive management through the year and from year to year. **Wildlife Interpretations:** Shadscale is a valuable browse species, providing a source of palatable, nutritious forage for a wide variety of wildlife particularly during spring and summer before the hardening of spiny twigs. It supplies browse, seed, and cover for birds, small mammals, rabbits, deer, and pronghorn antelope.

Hydrological functions

Runoff is medium to very high. Permeability is moderately rapid. Hydrologic soil group D.

Recreational uses

Aesthetic value is derived from the diverse floral and faunal composition and the colorful flowering of wild flowers and shrubs during the spring and early summer. This site offers rewarding opportunities to photographers and for nature study. This site is used for hiking and has potential for upland and big game hunting.

Other products

Seeds of shadscale were used by Native Americans for bread and mush.

Type locality

Location 1: Clark County, NV	
Township/Range/Section	T20S R67E S14
General legal description	Lake Mead National Recreation Area, Clark County, Nevada. Approximately one mile west of Miner's Cove along the west side of the Overton Arm of Lake Mead.

Rangeland health reference sheet

Interpreting Indicators of Rangeland Health is a qualitative assessment protocol used to determine ecosystem condition based on benchmark characteristics described in the Reference Sheet. A suite of 17 (or more) indicators are typically considered in an assessment. The ecological site(s) representative of an assessment location must be known prior to applying the protocol and must be verified based on soils and climate. Current plant community cannot be used to identify the ecological site.

Composition (Indicators 10 and 12) based on	Annual Production

Indicators

1. **Number and extent of rills:** Rills are none to rare, but may be evident in areas recently subjected to summer convection storms.

2. **Presence of water flow patterns:** Waterflow patterns are none to rare. A few waterflow patterns may be evident in areas recently subjected to summer convection storms. Where flow patterns are observed, they are short in length and stable.

3. **Number and height of erosional pedestals or terracettes:** Pedestals are none to rare with occurrence typically limited to areas within waterflow patterns.

4. **Bare ground from Ecological Site Description or other studies (rock, litter, lichen, moss, plant canopy are not bare ground):**
Bare Ground 70-80%

5. **Number of gullies and erosion associated with gullies:** None

6. **Extent of wind scoured, blowouts and/or depositional areas:** None

7. **Amount of litter movement (describe size and distance expected to travel):** Fine litter (foliage from grasses and annual & perennial forbs) expected to move distance of slope length during intense summer convection storms or rapid snowmelt events. Persistent

litter (large woody material) will remain in place except during large rainfall events.

8. Soil surface (top few mm) resistance to erosion (stability values are averages - most sites will show a range of values): Soil stability values should be 1 to 3 on the soil textures found on this site. (To be field tested.)
-
9. Soil surface structure and SOM content (include type of structure and A-horizon color and thickness): Surface soil structure is typically moderate medium to moderate thin platy. Soil surface colors are light and soils are typified by an ochric epipedon. Organic matter of the surface 2 to 3 inches is less than 1 percent.
-
10. Effect of community phase composition (relative proportion of different functional groups) and spatial distribution on infiltration and runoff: Sparse shrub canopy and associated litter provide some protection from raindrop impact.
-
11. Presence and thickness of compaction layer (usually none; describe soil profile features which may be mistaken for compaction on this site): None. Platy or massive sub-surface horizons or gypsic horizons are not to be interpreted as compacted layers.
-
12. Functional/Structural Groups (list in order of descending dominance by above-ground annual-production or live foliar cover using symbols: >>, >, = to indicate much greater than, greater than, and equal to):
- Dominant: salt-desert shrubs > associated Mojave Desert shrubs
- Sub-dominant: perennial forbs > perennial bunchgrasses = annual forbs
- Other:
- Additional:
-
13. Amount of plant mortality and decadence (include which functional groups are expected to show mortality or decadence): Dead branches within individual shrubs common and standing dead shrub canopy material may be as much as 25% of total woody canopy; mature bunchgrasses commonly ($\pm 15\%$) have dead centers.
-
14. Average percent litter cover (%) and depth (in): Between plant interspaces and under shrubs up to 10 %.
-
15. Expected annual annual-production (this is TOTAL above-ground annual-production, not just forage annual-production): For normal or average growing season ± 200 lbs/ac. Favorable years 350 lbs/ac and unfavorable years 100 lbs/ac or less.
-
16. Potential invasive (including noxious) species (native and non-native). List species which BOTH characterize degraded states and have the potential to become a dominant or co-dominant species on the ecological site if their future establishment and growth is not actively controlled by management interventions. Species that become dominant for only

one to several years (e.g., short-term response to drought or wildfire) are not invasive plants. Note that unlike other indicators, we are describing what is NOT expected in the reference state for the ecological site: Invaders on this site include annuals such as red brome, redstem filaree, annual mustards, and Mediterranean grass.

17. **Perennial plant reproductive capability:** All functional groups should reproduce in average and above average growing season years. Little growth or reproduction occurs in drought years.
-
